

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Q. Please state your names and business addresses.

2 A. Our names are Lynn M. Urbano and Brian P. Daly and  
3 collectively we make up the Peak Demand Allocation  
4 Panel for this case. We are both employed by  
5 Consolidated Edison Company of New York, Inc. ("Con  
6 Edison" or "the Company") and our business address is  
7 4 Irving Place, New York, New York 10003.

8 Q. In what capacity are the panel members employed and  
9 what are their professional backgrounds and  
10 qualifications?

11 A. (Urbano) I am the Section Manager of Demand  
12 Forecasting within the Energy Management Department.  
13 I have been employed by Con Edison since 1994 with a  
14 short hiatus for a few years to pursue an MBA full-  
15 time. My current responsibilities include managing  
16 and leading a team of 12 analysts that develops the  
17 demand forecasts for electric, gas, and steam. I  
18 began employment in the Company's two-year management  
19 intern program. I held positions in Purchasing and  
20 Planning and Analysis before leaving the Company in  
21 September 1998 to pursue my MBA full-time, where I  
22 also worked part-time as a Graduate Assistant for two

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 professors in the Economics Department. I returned to  
2 the Company in January 2001 and held positions of  
3 increasing responsibility as a Senior Analyst and  
4 Senior Planning Analyst in Electric Forecasting (now  
5 known as Demand Forecasting) where my primary  
6 responsibility was the development of the system  
7 forecast by sector and tracking performance of  
8 economic variables. I have been the Section Manager of  
9 Demand Forecasting since August 2004. I earned a  
10 Bachelor of Science Degree in Mathematics from  
11 Manhattan College, Master of Business Administration  
12 (MBA) from Villanova University, and a Master of Arts  
13 in Economics from Hunter College, City University of  
14 New York.

15 (Daly) I am a Senior Planning Analyst in the Energy  
16 Management Demand Forecasting Section. I have been  
17 employed at Con Edison since 1974, and in the  
18 Forecasting section since 1986. My current  
19 responsibilities include constructing daily peak  
20 demand versus weather models, conducting the post-  
21 summer weather adjustment analysis, constructing full-  
22 service customer forecast models, and representing Con

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Edison and O&R as a member of the NYISO Load  
2 Forecasting Task Force. While employed at Con Edison,  
3 I have held supervisory positions in Credit and  
4 Collection, the Call Center, and Property Protection.  
5 I held an analytical position in Central Customer  
6 Service and was administrator of the electric meter  
7 portion of the capital budget. I earned a Bachelor of  
8 Science degree in Management from Mercy College and a  
9 Master of Science in Human Resource Management from  
10 Mercy College.

11 Purpose of Testimony

12 Q. What is the purpose of your testimony?

13 A. We respond to the direct testimony of Department of  
14 Public Service Staff Witness Anping Liu, as it relates  
15 to the Company's peak demand forecast. We respond to  
16 Mr. Liu's recommendations that (1) Con Edison reduce  
17 its 2008 weather adjusted peak demand by 200 MW, and  
18 (2) Con Edison's forecasted peak demand growth through  
19 the year 2013 should be reduced by 100 MW. This 100  
20 MW reduction by 2013 includes a proposed 25 MW  
21 reduction in commercial sector growth and 75 MW  
22 reduction for residential sector growth. In total,

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Mr. Liu decreases the Company's demand forecast by 300  
2 MW by 2013. As a result of the lower peak demand  
3 forecast, Mr. Liu suggests that the Company's capital  
4 infrastructure investment reflect the reduced peak  
5 demand level. The Company's IIP testimony addresses  
6 the investment reduction. Our rebuttal testimony  
7 explains the basis for our peak demand forecast, the  
8 various flaws in Mr. Liu's positions, and demonstrates  
9 that the Con Edison peak demand forecast for 2013 as  
10 originally submitted and based on the data at the  
11 time, was correct.

12 **Peak Demand Forecast**

13 Q. What are the responsibilities of the Demand Forecast  
14 section as it pertains to electric?

15 A. The Demand Forecasting section of the Resource  
16 Planning department in the Energy Management  
17 organization calculates daily, annual, and long-term  
18 electric peak demand forecasts. The electric demand  
19 annual and long-term analysis and forecast is  
20 conducted at the end of the summer for the following  
21 ten year period. It is the combination of the summer  
22 demand growth most recently experienced and the growth

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 expected to be realized over a ten year period from  
2 known projects, the economy, and consumer behavior. It  
3 is presented as the (1) Service Area Peak Demand  
4 Forecast and (2) Network Area Peak Demand Forecast.  
5 The electric demand forecasting process involves the  
6 weather adjustment process of demand experienced in  
7 the most recent summer, a top-down as well as a  
8 bottom-up evaluation for each of the major sectors in  
9 the economy (commercial & residential). The weather  
10 adjusted demand, the top-down and bottom-up process  
11 are reconciled to establish the peak demand forecast.  
12 So, for example, after the summer of 2007, the Company  
13 looked at the demand that was forecast and performed a  
14 weather adjustment to determine the weather adjusted  
15 demand. This weather adjusted demand, in combination  
16 with developing a top-down, bottom up forecast, lead  
17 to the development of a peak demand forecast for 2008.  
18 After the summer of 2008, the same process was  
19 repeated to develop the 2009 forecast.

20 Q. What is the Company's peak demand forecast?

21 A. The peak demand forecast is the amount of electric  
22 demand the Company believes will be required on a hot

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 summer day when certain design criteria are met for  
2 both the system, as a whole, and in networks,  
3 individually. The design criteria are explained  
4 below. The Company expects that it will engineer and  
5 build its system to meet this projected peak summer  
6 day. The forecast is based on several scenarios  
7 including approaching the forecast from a bottom-up  
8 and top-down perspective.

9 Q. Please describe what is meant by a top-down, bottom-up  
10 process.

11 A. The peak demand forecasting process involves a top-  
12 down as well as a bottom-up evaluation for each of the  
13 major sectors in the economy, which includes the  
14 residential and commercial sectors. From a top-down  
15 perspective, the commercial demand forecast is based  
16 on an econometric model that reflects the economic  
17 inputs Private Non-Manufacturing employment and U.S.  
18 Gross Domestic Product ("GDP"), and a few other  
19 variables. The top-down residential demand forecast  
20 is based on an appliance end-use model that reflects  
21 projections of the number of households, saturation of  
22 appliances, household occupancy, coincident use of

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 appliances, and appliance efficiency based on  
2 government standards. We would like to define some of  
3 the inputs to the model that need some explanation.

4 Q. Please provide those definitions.

5 A. Saturation is defined as the percentage of households  
6 that have a particular appliance; household occupancy  
7 is the percentage of households estimated to be  
8 occupied during the time of the system peak demand;  
9 and coincident use of an appliance is the percentage  
10 of a particular appliance that is on, e.g., consuming  
11 electricity, at the time of the system peak demand.

12 Q. Please continue.

13 A. The purpose of utilizing these two methodologies is  
14 primarily motivated by the fact we must also forecast  
15 the electric peak demand for not only the system in  
16 its entirety but for each network area within Con  
17 Edison's service territory, which includes New York  
18 City and Westchester County. Without a bottom-up  
19 approach, all top-down system demand growth would be  
20 allocated to the network areas based on an allocation  
21 methodology and not based on any actual construction  
22 growth expected to take place in that network. The

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 forecast, however, cannot be developed with just the  
2 bottom-up methodology. The top-down approach is an  
3 important aspect of the forecasting process and it is  
4 necessary for several reasons: it looks at many  
5 different factors that influence the level of demand  
6 growth; it provides a long-term trend based on growth  
7 in these factors; and it provides growth of existing  
8 customers that cannot be captured by new construction  
9 activities. Therefore, the top-down approach is  
10 supplemented by a bottom-up approach that reflects  
11 construction activities in specific network areas.  
12 Through the use of both of these methodologies, each  
13 individual network area forecast is developed based on  
14 known construction activities in the appropriate areas  
15 and through the allocation of system growth of  
16 existing customers.

17 Q. What is a system peak?

18 A. The system peak is the highest one-hour integrated  
19 demand experienced during each year. The all-time  
20 system peak is the highest annual peak ever achieved.  
21 For Con Edison, the all-time system peak is 13,141 MW,  
22 and it occurred on August 2, 2006. Since that time,

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 we have had three consecutive cooler than normal  
2 summer periods (July and August), which has not  
3 resulted in a new system peak being established.

4 Q. What is a network peak?

5 A. Unlike the system as a whole, the peak for each  
6 network area is represented in two ways - on both an  
7 independent and coincident basis. By independent, we  
8 mean the peak specific to a network, whenever that may  
9 have occurred and by coincident, we mean the network  
10 peak demand that occurred simultaneous with the  
11 service area peak day and time.

12 Q. Does the Company expect to set an all-time peak demand  
13 day every summer, for either the system or for each  
14 network?

15 A. No. All peaks are completely weather dependent.  
16 While every summer will have a peak day, very high  
17 peaks near or exceeding the all-time system, or  
18 network, records are expected to occur as we near or  
19 exceed our design criteria, which are projected to  
20 occur once every three years.

21 Q. Why is forecasting the system and network peaks  
22 properly so important?

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 A. The prime importance of both is to ensure and maintain  
2 electric delivery reliability, which is critical for  
3 the economic growth of the region and the health and  
4 well being of our customers. The New York Independent  
5 System Operator ("NYISO") is responsible for state-  
6 wide reliability issues. The system peak demand  
7 forecast is important because it is a direct input  
8 into the NYISO determination of installed capacity  
9 ("ICAP") requirements for the State as a whole, and  
10 for New York City's distinct locational requirements  
11 in the electricity market. Proper forecasting of the  
12 networks is important because the reliability  
13 requirements of the network area forecast drive the  
14 Area Station Ten-Year Load Relief Plan, directly  
15 affecting the Company's transmission and distribution  
16 ("T&D") capital budget

17 Q. Please further explain the Network Area Peak Demand  
18 Forecast.

19 A. The Demand Forecasting Section is responsible for the  
20 evaluation and analysis of the electric peak  
21 experience for each of the Company's network areas.  
22 The purpose of the analysis is to develop a weather

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 adjusted, base-year peak demand, for each network  
2 area, and as mentioned before, on a coincident and  
3 independent basis. Most significant of the two in  
4 terms of the T&D budget is the independent weather  
5 adjusted peak demand because it serves as the basis  
6 for the Network Area Peak Demand Forecast, which, in  
7 turn, becomes the foundation of the Area Station Ten-  
8 Year Load Relief Plan.

9 Q. What happens if the forecasted demand is too low or  
10 too high as compared to the adjusted demand?

11 A. If the demand is underestimated, reliability can be  
12 jeopardized because the Company will not have  
13 properly prepared for the amount of demand to be  
14 experienced in either a single network, several  
15 networks or the system as a whole during the upcoming  
16 summer. If the demand is overestimated, it could  
17 possibly mean that T&D improvements were made  
18 unnecessarily or ahead of actual requirement  
19 timeframe, thus potentially increasing rates. Either  
20 situation is undesirable, either from a Company or  
21 customer perspective. In fact, the reliability  
22 performance mechanism that the Company is subject to

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 penalizes the Company for failure to meet its  
2 reliability criteria.

3 Q. How does Con Edison "weather adjust" the peak  
4 experience of a particular year, and why is it  
5 important?

6 A. Con Edison uses a weather concept called Temperature  
7 Variable ("TV") as a reference point used in designing  
8 its electric transmission and distribution systems.  
9 The TV is the Company's design criteria. It is used  
10 in calculating and forecasting future system peak  
11 demands, taking into account near extreme summer  
12 weather conditions -- sustained high temperatures and  
13 humidity over a three-day period -- that we would  
14 expect to experience in the metropolitan New York area  
15 in one of every three years. The system design TV  
16 used by Con Edison is 86°F (dry bulb-wet bulb  
17 average). At its simplest, there is an expectation  
18 that annual observed peak demands that occur at a TV  
19 less than design would be adjusted upward, while the  
20 observed peak demands occurring at a TV greater than  
21 design would be adjusted down.

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1           However, Con Edison does not adjust a "single" point.  
2           It is much more representative to arrive at a final  
3           determination of the annual adjusted peak demand after  
4           considering all of the weekday peak versus weather  
5           responses to mitigate the potential bias of a single  
6           day.

7    Q.    Please continue.

8    A.    In the weather adjustment process, weekday peak  
9           demands for July and August (sometimes very late June)  
10           are included in the analysis. Peaks are evaluated and  
11           modified (or "rebuilt") to account for the impact of  
12           demand mitigation measures, such as:

13           a.    Demand reduction programs, either self-invoked  
14           programs, such as the Company's Distribution Load  
15           Relief Plan or ("DLRP") programs, or emanating from  
16           the NYISO, such as the Emergency Demand Response  
17           Program ("EDRP") or Special Case Resources ("SCR") or  
18           NYPA's Peak Load Management Program. These programs  
19           enroll customers that can reduce their demand when  
20           notified to do so (for which they receive a payment of  
21           some sort). The programs are usually invoked to

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

- 1       relieve some strain on either the transmission or  
2       distribution systems.
- 3       b.    Voltage reductions are actions that can be  
4       invoked by either the NYISO or Con Edison's System  
5       Operation department to reduce voltage levels that are  
6       being provided to customers in a manner that does not  
7       harm equipment or appliances, thereby reducing demand.
- 8       c.    Significant outages which can be defined as the  
9       loss of an entire network or a significant portion  
10      thereof.
- 11      d.    Friday or pre/post-holiday impact, which means  
12      that generally during the summer, people leave the  
13      service territory on Fridays or pre-holidays and  
14      therefore, demand is less than it otherwise would have  
15      been.
- 16    Q.    Why are peaks evaluated and rebuilt to account for  
17      demand mitigation measures?
- 18    A.    Since all weekday peaks are evaluated in one process,  
19      it is necessary to represent each day as if no  
20      mitigation measures were taken.  By not doing so, the  
21      peaks experienced (most likely occurring at the high

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 end) will be understated, as will the resulting final  
2 adjusted demand.

3 Q. Does the Company include early June peaks in its peak  
4 forecast?

5 A. Historically, we have not used early June peaks in our  
6 analysis because we do not believe that early June  
7 peak response would be representative of a true summer  
8 peak. Our peak-eliciting design conditions are driven  
9 by residential air-conditioning use, after an  
10 installation ramp-up period as weather progressively  
11 warms. We believe that the full impact of residential  
12 air-conditioning is not manifested until we reach a  
13 mature level of installation, which usually occurs by  
14 July.

15 Q. Is there a relationship between peak demand and TV?

16 A. Yes. Weekday peak demands, whether original or  
17 modified ("rebuilt") and their corresponding TVs are  
18 graphically represented to demonstrate a relationship  
19 between the two. Several standard regression models  
20 (or "best fit") analyses are used to estimate what the  
21 peak demand would have been at the design TV criteria  
22 of 86°F.

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Q. Please explain what the Panel means by "best fit."

2 A. While we use standard regression analysis as part of  
3 the adjustment process, "best fit" to us does not  
4 necessarily mean best "statistical" fit. Instead, the  
5 curve fit is a tool that we use to establish the most  
6 reasonable adjusted peak range at our design criteria  
7 of 86°F TV.

8 Q. Why are regressions performed on the results of the  
9 peak demand TV?

10 A. Regression analysis is a standard tool used to  
11 determine the relationship between variables - in this  
12 case, peak demand and weather.

13 Q. Is a regression analysis the only component of the  
14 weather adjustment process?

15 A. No. It is important to note that regression results  
16 alone do not dictate the final determination of the  
17 adjusted demand process. Several regression model  
18 views are usually performed in an effort to narrow the  
19 range of estimated demand response to the design  
20 criteria. This is especially true in those years  
21 where there is an absence of data points across the TV  
22 spectrum, most notably at the top end. To corroborate

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 results from regressions, input is solicited from  
2 other analysts performing the network area  
3 adjustments, network area review of construction  
4 activity, and general economic review.

5 Q. What input is provided and how does that fit into your  
6 process?

7 A. Solicited input may typically include results from the  
8 residential end-use model, updated economic data from  
9 Moodys-Economy.com, large customer account demand  
10 analysis, and updates on the phasing of particularly  
11 large construction projects. We would also like to  
12 note that this is a non-additive process. By non-  
13 additive, we mean that the other intelligence or input  
14 solicited does not become part of a mathematical  
15 formula, but instead is intended to assist in trend  
16 recognition.

17 Q. Have you ever detailed the adjustment process before?

18 A. Yes, we have. In the Management Audit conducted by  
19 Liberty Consulting, we explained our process to  
20 Liberty.

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Q. Were any objections raised or corrections requested to  
2 the Con Edison adjustment process by the Liberty  
3 Audit?

4 A. No. In fact, the Liberty Audit stated the following:

- 5 • CECONY's fundamental approach to load forecasting,  
6 which features multiple approaches to developing  
7 electric peak demands, is sound, and includes  
8 quality inputs and tools (Page VII-29).
- 9 • The models employed by the Company in its electric  
10 load forecasting activities are sound, tested, and  
11 effective in their intended use (Page VII-30).
- 12 • Models used in load forecasting are well-managed,  
13 including appropriate updating and revision as well  
14 as control of quality. (Page VII-30).

15 Q. Has Mr. Liu or any other Staff member previously  
16 objected to the Company's peak demand forecasting  
17 process in prior rate cases?

18 A. To our knowledge, no. And, in fact, the Company has  
19 been using this forecasting methodology for more than  
20 20 years.

21

22

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 2008 PEAK FORECAST

2 Q. What is the Company's 2008 Weather adjusted peak  
3 demand?

4 A. As noted by Mr. Liu, the actual peak demand for 2008  
5 was 12,987 and the weather adjusted peak demand is  
6 13,700.

7 Q. Was an all-time system peak realized in 2008?

8 A. No. As stated earlier, the all-time actual system  
9 peak is 13,141 MW reached on August 2, 2006. The  
10 weather in 2007 and 2008 did not reach temperatures  
11 where we would have expected to see a new system peak.  
12 The same is true in 2009.

13 Q. Mr. Liu states (p. 6) that the Company uses a model  
14 with a flawed assumption that contradicts theory and  
15 evidence. Do you agree?

16 A. No. Mr. Liu focuses solely on the statistical output  
17 of a modeling technique.

18 Q. What does he say about the relationship of air  
19 conditioning demand to temperature?

20 A. Mr. Liu contends that the pattern of temperature  
21 response to demand is that as the temperature  
22 increases, demand will increase. But, the pattern

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 will reverse once the temperature reaches a certain  
2 point. At the point where the temperature nears or  
3 exceeds the expected peaking conditions, cooling  
4 appliances reach full capacity. As a result, each  
5 degree increase in temperature leads to smaller  
6 response in demand and the rate of demand response to  
7 temperature decreases.

8 Q. Do you agree with this statement?

9 A. We agree with the generality of the statement, but  
10 disagree that the peak response begins to abate as the  
11 design criteria is reached. We believe that the peak  
12 ramp rate will be consistent up to design, and abate  
13 thereafter.

14 Q. On page 10, lines 15-17, Mr. Liu asserts that Con  
15 Edison summer models in general are partially U-  
16 shaped. Do you agree with this characterization?

17 A. No. The term "U-shape" or even "partially U-shaped"  
18 implies a line with a deep or sharp bend in the body  
19 of the graphical representation of the model. The  
20 curves that is included in Exhibit \_\_ (AL-2, page 3)  
21 that Mr. Liu is referring to, while reflecting a soft  
22 bend, show nothing that can be construed as a deep or

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 sharp bend. Additionally, the X-Axis scale on Exhibit  
2 \_\_\_ (AL-2, page 3) reflects a maximum TV of 96°F.  
3 Since historically (from 1953) the TV has never  
4 reached 90°F, referring to the model as partially "U"  
5 shaped and including six additional degrees implies a  
6 results-oriented analysis.

7 Q. On page 10, lines 17-22, Mr. Liu states that,  
8 "Unrealistically, Con Edison's assumption implies that  
9 cooling appliance capacity is not a finite number, and  
10 it will not start reaching full capacity even when the  
11 temperature goes above the design weather conditions."  
12 Do you agree with this statement?

13 A. We have never implied that our models, although  
14 containing a soft bend upward, are applicable beyond  
15 the design of 86°F. In fact, we specifically have  
16 stated to various involved people - Staff, the NYISO,  
17 and internal personnel -- that we expect a ramp of  
18 about 300 MW of demand per degree of temperature  
19 increase up to and including a TV of 86°F, and a  
20 reduced ramp rate of 150 MW per degree beyond a TV of  
21 86°F. Again, this mischaracterization that there is  
22 an infinite ramp-up implies that Mr. Liu either

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1           misunderstands the Company's model or that he is  
2           performing an analysis to come up with a particular  
3           result.

4    Q.    Please comment on Mr. Liu's statement (p. 11) that the  
5           demand temperature relationship is not partially U-  
6           shaped for temperatures above normal weather  
7           conditions and his claims that a recent demand  
8           forecast uncertainty study performed by the NYISO  
9           supports his theory.

10   A.    On page 17, lines 7-11, Mr. Liu states that at design  
11           weather conditions, the NYISO estimated the Con Edison  
12           system peak for 2008 at approximately 13,500 MW. In  
13           the exhibit referenced, Exhibit \_\_ (AL-2, page 5) the  
14           design temperature listed is in Composite Temperature  
15           Humidity Index (CTHI), the NYISO's weather component,  
16           not TV, which is the Con Edison weather component.  
17           Additionally, the demand corresponding to the design  
18           listed on the exhibit would be less than 13,000 MW  
19           which would severely understate Con Edison's system  
20           peak. Actually, we could not find the 13,500 MW Mr.  
21           Liu refers to. In fact, in that same report (page  
22           22), the NYISO reflects a 2010 forecasted demand of

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 13,750 MW, which is consistent with the Con Edison  
2 forecast.

3 Q. Do you agree with Mr. Liu's findings and  
4 recommendations that the peak demand adjustment for  
5 2008 be reduced by 200 MW?

6 A. No, we do not. Mr. Liu's analysis is based solely on  
7 his pooled regression model. The pooled regression,  
8 on its own, is a thorough and accurate methodology,  
9 and the results of the model can be considered to be  
10 statistically sound. Since Mr. Liu focuses solely on  
11 statistic driven results and fails to recognize the  
12 reliability risk associated with under-forecasting at  
13 the design criteria of 86°F, his 200 MW reduction to  
14 the 2008 peak should be rejected.

15 Q. Has the Company ever used a pooled regression model?

16 A. Yes. In fact, we actually used a variation of it this  
17 year to gauge year-over-year peak changes from 2008 to  
18 2009.

19 Q. What other information should be used to consider the  
20 validity of the forecast?

21 A. After standard regression methodology, we look at peak  
22 response in the upper TV range, specifically around

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

- 1           86°F. That does not mean to imply that we ignore  
2           higher or lower than the design TV of 86°F. Our prime  
3           focus for design purposes is peak at 86°F.
- 4   Q.   What are the drawbacks of only using a final fit or  
5           demand adjustment based solely on statistical best  
6           fit?
- 7   A.   Regression analysis essentially will find the middle  
8           ground between a set of data points. If this middle  
9           ground undercuts actual data points at the top end,  
10          the difference would be attributed to model  
11          "variability." The resultant adjustment at the design  
12          TV, while statistically acceptable, could be set too  
13          low, thereby jeopardizing system reliability.
- 14   Q.   Was this the result of Mr. Liu's pooled methodology?
- 15   A.   Yes. When we adjusted the 2006 data points, we did  
16          not include those over 87°F TV specifically because it  
17          tended to suppress the estimated peak response at  
18          86°F. Mr. Liu did include those points, with the net  
19          result that his estimation of peak response would  
20          always be lower than the actual peak experienced below  
21          87°F.
- 22   Q.   How does Mr. Liu's model perform over 87°F?

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 A. Very well, but as we stated, it compromised the peaks  
2 around 86°F. This suggests that Mr. Liu's forecasting  
3 method is not representative of the weather and the  
4 peaks.

5 Q. Mr. Liu claims that pooling the four years worth of  
6 data allows him to forecast the peak despite the  
7 absence of warm days in 2007 and 2008. Do you agree?

8 A. While pooled analysis is a statistically valid  
9 approach, we believe that the absence of hot days in  
10 2007 and 2008 (and now 2009) leads to assumptions that  
11 can seriously jeopardize reliability, especially when  
12 the outcome has no flexibility in terms of range  
13 assessment.

14 Q. On page 16, lines 14-23, Mr. Liu questioned our mid-  
15 range peak versus TV analysis for 2007 and 2008 that  
16 showed a 1.1% growth. He agreed that there was a 1.1%  
17 difference, but he specifically objected to applying  
18 the 1.1% to higher-end 2007 data points as a proxy,  
19 saying that, "Con Edison assumed that the temperature  
20 response is constant at the middle to higher  
21 temperatures and increasing as the temperature goes

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 even higher near design conditions. This is counter-  
2 intuitive". Do you agree with his statements?

3 A. No. In fact, the Con Edison analysis used actual  
4 comparative 2007 and 2008 data up to about 82°F TV,  
5 and then applied the 1.1% to actual 2007 points beyond  
6 the 82° threshold at 82.3°F, 83.1°F, and 83.2°F. The  
7 data was not extrapolated to the full design level of  
8 86°F. We did not imply that the 1.1% would grow as it  
9 reached 86°F, but instead that it maintained a  
10 relative consistency, and believe it was a reasonable  
11 approach. Mr. Liu's own analysis indicates that the  
12 ramp rate from 81°F to 86°F starts at 2.4% and slows  
13 down to 1.9%, but does not reflect a complete  
14 compression of the demand response.

15 Q. To summarize, do you agree with Mr. Liu's  
16 recommendation that Con Edison reduce its 2008 weather  
17 adjusted peak demand by 200 MW?

18 A. No, we do not for the following reasons:

19 • The sole basis for his recommendation is a  
20 statistical output of four years of data, the last  
21 two of which did reach near design conditions of

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1           86°F TV. The conclusion is fixed and inflexible and  
2           does not allow for range consideration.

3           • Mr. Liu's analysis, while statistically valid, would  
4           seem to understate the peak demand at the most  
5           critical juncture, the design range in and around  
6           86°F TV, which could jeopardize system reliability.

7           • The Con Edison methodology has been used  
8           successfully for more than 20 years without  
9           challenge.

10          • As explained below, our preliminary 2009 weather  
11          adjustment has already resulted in a reduction of  
12          125 MW from the 2009 weather adjustment of 13,700  
13          MW. Anything more than that at this point,  
14          especially with the absence of higher TV peak  
15          demands for the past three years, could jeopardize  
16          reliability.

17   Q.    Do you plan on modifying your adjustment process  
18          moving forward?

19   A.    We are currently benchmarking several utilities across  
20          the country to indentify "best" practices, which is  
21          also a recommendation contained in the Liberty audit.

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Q. Since you are now in the midst of the 2009 adjustment  
2 process, what have your preliminary 2009 adjustment  
3 findings been?

4 A. Our preliminary peak adjustment for 2009 is 13,575 MW,  
5 125 MW less the 2008 adjusted peak of 13,700 MW. It  
6 is our understanding that this preliminary 2009 peak  
7 data will be incorporated into the Ten-Year Area  
8 Substation Plan which is developed after the  
9 conclusion of the summer. Any investment changes  
10 resulting from this changed forecast are undetermined  
11 at this point since the Ten-Year Plan has not been  
12 developed. The IIP also discusses this issue and the  
13 Company's plan to update its revenue requirement.

14 Q. Why is the adjustment lower?

15 A. Our lower adjustment primarily reflects the continued  
16 impact of general economic conditions on the projected  
17 peak.

18 Q. Is the new five-year forecast lower as well?

19 A. Yes. The peak forecast being challenged by Mr. Liu  
20 reflects a 2013 peak of 14,455 MW. Mr. Liu has stated  
21 the 14,455 MW should be reduced by 100 MW based on his  
22 residential and commercial adjustments. The current

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 preliminary forecast, starting with the 2009 weather  
2 adjustment, reflects a 2013 peak of 14,225 MW, which  
3 is a reduction of 230 MW, and is based on more recent  
4 economic data. This does not mean that the Company  
5 accepts Mr. Liu's adjustment, which he would  
6 presumably deduct from the Company's forecasted peak  
7 reduction. This is simply the latest forecast which  
8 results from a complete analysis of the 2009 actual  
9 information as well as a top-down and bottom-up  
10 evaluation.

11 Q. Does this mean that you are partially agreeing with  
12 Mr. Liu in that you are reducing the forecast by 230  
13 MW of the 300 MW he suggested?

14 A. No. Mr. Liu's testimony pertains specifically to  
15 current Con Edison forecast, with a 2008 adjusted peak  
16 demand of 13,700 MW and the methodology used to create  
17 it. We are responding to his criticism of that  
18 forecast, and explaining the methodology, including  
19 the data used at that time. His recommendation to  
20 reduce the overall forecast by 300 MW included a 200  
21 MW reduction in the 2008 peak demand adjustment from

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 13,700 MW base point to 13,500 MW. We believe that  
2 the 2008 adjusted demand of 13,700 MW was correct. [

3 Q. Please continue.

4 A We stated above that the preliminary 2009 peak demand  
5 analysis is reflecting an adjusted demand of 13,575  
6 MW, or 125 MW less than the adjusted demand of 13,700  
7 MW. It is possible that Mr. Liu would argue that the  
8 125 MW reduction should be made against his suggested  
9 2008 adjusted peak demand of 13,500 MW, thus making  
10 the 2009 adjusted peak demand 13,375 MW. His argument  
11 would be incorrect as we have explained how the 2008  
12 forecast was sound.

13 Q. Since there is a preliminary decrease in the system  
14 forecast, does this mean that T&D investment should be  
15 reduced?

16 A. No. As we said previously, in addition to each  
17 network contributing to the system peak, each network  
18 also has an independent peak that will drive the T&D  
19 budget. Once the network area analysis is completed,  
20 there may be some individual networks that continue to  
21 reflect growth, especially in the residential sector

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Failure to properly design for each network will  
2 jeopardize system reliability.

3

4 2013 FORECAST FOR RESIDENTIAL AND COMMERCIAL

5 Q. What adjustments did Mr. Liu make to the system  
6 forecast?

7 A. Mr. Liu reduced the commercial and residential  
8 forecasts by 25 MW and 75 MW, respectively, by 2013.

9 Q. Do you agree with Mr. Liu's assessment that the  
10 commercial forecast should be reduced by 25 MW over  
11 the next five years?

12 A. No.

13 Q. Please explain why you disagree with his assessment.

14 A. Mr. Liu's testimony overlooks and understates the  
15 significance of the bottom-up perspective of the  
16 forecasting process. Mr. Liu's methodology is too  
17 narrow and, therefore, an incomplete approach for  
18 modifying the commercial forecast. Mr. Liu correctly  
19 explained on page 17 of his testimony that, "Con  
20 Edison combines top-down and bottom-up approaches to  
21 forecast the system peak demand." But to develop his  
22 adjustment, he only utilizes the top-down methodology.

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 Updating the commercial sector forecast for this one  
2 component undermines the forecasting process since Mr.  
3 Liu did not review and update, as necessary, other  
4 inputs to the forecast.

5 Q. Can those other inputs be updated?.

6 A. No. We cannot accurately assess the true impact of  
7 the reduction in the commercial sector on the system  
8 or network forecast as of the time of the T&D forecast  
9 because construction project information is fluid and  
10 it is not practical to maintain point-in-time  
11 iterations.

12 Q. Please continue.

13 A. Since the corresponding forecast for each network area  
14 is prepared by allocating the system-wide growth among  
15 networks with specific consideration for new  
16 construction, Mr. Liu's approach disregards one-half  
17 of the forecasting approach utilized to determine the  
18 system growth.

19 Q. Did Liberty review the Company's forecasting approach?

20 A. Yes. The Liberty Audit Report, page VII-29, states  
21 that "CECONY's fundamental approach to load  
22 forecasting, which features multiple approaches to

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 developing electric peak demands, is sound, and  
2 includes quality inputs and tools." Also on page VII-  
3 30, Liberty states "Models used in load forecasting  
4 are well-managed, including appropriate updating and  
5 revision as well as control of quality."  
6 Q. How would Mr. Liu's adjustment affect the forecast?  
7 A. By relying solely on one part of the forecasting  
8 process to make his assessment, Mr. Liu cannot make a  
9 proper adjustment. Any reduction Mr. Liu asserts  
10 should be made to the commercial forecast at a system  
11 level needs to also be reduced at a network level.  
12 Typically, growth from construction projects is  
13 reviewed in conjunction with the trend in growth from  
14 the commercial econometric model to determine the  
15 incremental growth in the commercial sector. The  
16 forecasted growth ultimately needs to capture the  
17 total growth in this sector, but the top-down process  
18 and bottom-up process are different ways of looking at  
19 the growth in the peak demand. It is important to  
20 review the results of both when developing the  
21 forecast and making any revisions to it. The risk of  
22 not doing so could be an incorrect amount of growth

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 being added to or taken away from the forecast in a  
2 particular year compared to the specific projects in  
3 the forecast for that given year. The econometric  
4 model results are useful as a means to determine the  
5 trend in growth over the entire 10-year forecast  
6 horizon and provide information on growth of existing  
7 customers.

8 Q. When Mr. Liu states on page 18 of his testimony that  
9 "the economic inputs to Con Edison's commercial peak  
10 demand forecast are inconsistent with the economic  
11 inputs to Con Edison's T&D revenue forecast" and on  
12 page 19 that "the economic inputs to Con Edison's T&D  
13 revenue forecast were provided at a later date and  
14 should also be used for the commercial peak demand  
15 forecast", is his assessment correct and does his  
16 rationale justify changing the commercial forecast?

17 A. As we have explained, the demand forecast is needed by  
18 a certain time so that the T&D capital budget (based  
19 on the 10 -year relief plan) can be developed in order  
20 to plan for the following summer and beyond. The  
21 demand forecast was updated from the fall 2008  
22 issuance to an updated forecast in the winter of 2008

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 to account for the decline in the economy. The revenue  
2 forecast was updated shortly after the demand forecast  
3 was updated. However, the timing of each forecast was  
4 not so different as to make a significant difference  
5 in the commercial forecast on a system basis. A 25 MW  
6 reduction over a five-year period equates to a 5 MW  
7 reduction per year. However, this reduction needs to  
8 also be placed on the network area forecast without  
9 consideration of the bottom-up process. Therefore,  
10 Mr. Liu's adjustment does not accurately assess  
11 whether the demand forecast for the commercial sector  
12 should be changed. We do not agree with his assertion  
13 that the commercial forecast should be decreased by 25  
14 MW by 2013 based on all the reasons given in this  
15 testimony.

16 Q. Do you agree with Mr. Liu's statement on page 20 of  
17 his testimony that, "The Company's forecast for the  
18 residential peak demand growth is overstated and  
19 should be reduced by 75 MW over the next five years"?

20 A. No, we do not agree with Mr. Liu's assessment and  
21 rationale behind the 75 MW reduction to the  
22 residential sector's demand forecast. Mr. Liu states

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 on page 21 of his testimony that his "adjustment  
2 results from assuming slightly lower growth rates of  
3 appliance saturation than the levels that Con Edison  
4 assumed for consistency with the historical trend and  
5 the current economic forecast in Con Edison's service  
6 area". While the Company uses recent historical  
7 trends to gauge the potential future growth in  
8 appliance saturation in the service territory, it also  
9 forecasts based on potential future trends in  
10 appliance ownership.

11 Q. Please continue.

12 A. Mr. Liu's assessment does not consider the fact that  
13 over time, appliances, such as air conditioners,  
14 become less of a luxury item for households and that  
15 prices of appliances come down over time, making them  
16 more affordable. In addition, people can choose to  
17 use air conditioners only on the hottest and most  
18 humid days, allowing them to save money when the  
19 weather is not extremely hot, but use it when needed  
20 most.

21 Q. What other factors cause you to disagree with Mr.  
22 Liu's reduction to the residential demand?

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 A. The residential forecast's main economic input is the  
2 number of households, which is linked to population  
3 growth. At the time of the development of the demand  
4 forecast in question (with an adjusted 2008 peak  
5 demand of 13,700 MW) actual population data showed an  
6 average annual growth rate of 0.3% per year over the  
7 period 2003-2008 and a forecast of 0.3% per year over  
8 the next five years (2008-2013). If the population is  
9 expected to continue to grow, new households will be  
10 created and/or vacant ones will be filled, which leads  
11 to growth in saturation of appliances. Mr. Liu states  
12 that "employment and real personal income are two of  
13 the key determinants of electric consumption and  
14 electronic appliance ownership."

15 Q. Do you agree?

16 A. No. His statement is misleading. The statement does  
17 not speak specifically about annual peak demand, which  
18 is the highest usage during one hour of the year, but  
19 instead refers to consumption, which we define as  
20 usage over the course of a 24 hour day for 365 days a  
21 year. The Company must plan for the demand of  
22 residential customers in one hour of a hot and humid

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 summer day, which may only require one heat wave to  
2 occur, as opposed to consumption, which people can  
3 vary depending on weather and other factors over the  
4 course of a year.

5 Q. What is the primary driver of residential demand?

6 A. The residential electric peak demand is primarily  
7 driven by air conditioning usage on a hot and humid  
8 day or several days of hot and humid weather.

9 Q. Can the economy and weather possibly affect this  
10 driver?

11 A. Yes, that is possible. However, on pages 21 and 22,  
12 Mr. Liu cites the fact that "employment growth over  
13 the next five years is forecasted to be approximately  
14 one-third of that observed in the last three to five  
15 years and real personal income growth for the next  
16 five years is expected to be less than one-half of the  
17 level observed over the past five years" as his  
18 rationale for reducing the saturation levels of  
19 appliances by 2013. While the growth in employment  
20 and personal income may be slower for 2008-2013  
21 compared to 2003-2008 and 2005-2008, the link between

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1           these indicators and peak demand is not present as Mr.  
2           Liu suggests.

3    Q.    Please continue.

4    A.    In the period 2000-2005, the adjusted system peak  
5           demand increased at an average annual growth rate of  
6           2.1%.  during the same period, personal income  
7           increased at an average annual growth rate of 3.6% and  
8           private non-manufacturing employment declined at an  
9           average annual growth rate of 0.2%, as calculated from  
10          the data on page 7 of 11 in Mr. Liu's workpapers.  
11         Comparing these rates to the ones Mr. Liu uses for his  
12         testimony for the time period 2008-2013, which are  
13         3.1% average annual growth rate in personal income and  
14         0.6% average annual growth rate growth in employment,  
15         we believe that the argument cannot be made that the  
16         growth in these specific economic indicators will  
17         necessarily trend in the same direction or magnitude  
18         for peak demand, as shown in 2000-2005.

19    Q.    Are there other factors that you disagree with in the  
20           suggested reduction of the residential demand forecast  
21           by 75 MW by 2013?

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 A. Yes. It is also possible that residential demand can  
2 experience some years of slow growth, negative growth,  
3 and then a period of faster growth that get you to the  
4 healthy final demand forecasted by 2013. Using Mr.  
5 Liu's logic about growth in personal income and  
6 employment affecting appliance saturation growth,  
7 since the forecasted growth rates for both of these  
8 economic variables are positive (4.8% for personal  
9 income from 2009 to 2013 and 1.7% for private non-  
10 manufacturing employment for the same time period) and  
11 close to historical levels, one could assume that  
12 saturation would also increase during this period. An  
13 increase in saturation would result in a bounce back  
14 of the residential appliance saturation and demand by  
15 2013.

16 Q. Are there any other factors that Mr. Liu fails to  
17 consider in his analysis?

18 A. Yes. As with the commercial forecast, Mr. Liu  
19 ignores the fact that both a top-down and bottom-up  
20 approach is taken to develop the residential forecast.  
21 Without a bottom-up approach, all of the top-down  
22 system demand growth decline proposed would be

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 allocated to the network areas based on an allocation  
2 methodology and not based on any actual residential  
3 construction growth, or lack thereof. In addition,  
4 the bottom-up evaluation cannot be completed to  
5 determine if the decline is reasonable or necessary  
6 since we cannot assess the construction project  
7 information at the time the T&D forecast was issued.  
8 Reducing saturation growth is not realistic based on  
9 the reasons stated by Mr. Liu and his numbers are a  
10 judgment based on economic indicators that have not  
11 historically been linked to declines in demand. Mr.  
12 Liu's assessment is a results-oriented analysis which  
13 does not utilize the correct indicators or a complete  
14 process to make his conclusion. Therefore, we do not  
15 agree that the residential demand should be reduced by  
16 75 MW.

17 Q. Are there any other considerations to be addressed  
18 with regard to reducing the commercial and residential  
19 forecasts without completing the top-down and bottom-  
20 up forecast?

21 A. Yes. The Liberty Audit points out on page VII-10 that  
22 "the longer-term demand forecasts (for electric

PEAK DEMAND ALLOCATION PANEL - REBUTTAL  
ELECTRIC

1 demand) have been consistently under-estimating the  
2 peak." Mr. Liu's adjustments to the forecasts for  
3 commercial and residential sector growth are likely to  
4 continue the under-forecasting of the long-term  
5 demand.

6 Q. Does this conclude the Panel's rebuttal testimony?

7 A. Yes, it does.
